How do you calculate the energy stored in a coil?

The energy stored in a coil can be calculated using the formula $E = \frac{1}{2} * L * I^2$, where E is the energy, L is the inductance, and I is the current flowing through the coil. For example, in a coil of resistance 50 and inductance 4 H connected to a 10 V battery, the energy stored in the coil can be found by first calculating the current flowing through the coil.

Energy Storage. Electric coils are often used in energy storage, especially in inductive components like inductors and chokes. The maximum capacity of the energy storage is $E_{\max} = \frac{1}{2} L I_c^2$, where L and I_c are the inductance and critical current of the superconductor coil respectively. It is obvious that the E_{\max} of the device depends merely upon the properties of the superconductor coil, i.e., the inductance and critical current of the coil. Besides E_{\max} , the capacity realized in a practical ...
