What is energy storage in an inductor?

Energy storage in an inductor is a function of the amount of current through it. An inductor's ability to store energy as a function of current results in a tendency to try to maintain current at a constant level. In other words, inductors tend to resist changes in current.

How does a Magnetic Inductor store more energy?

To store more energy in an inductor, the current through it must be increased. This means that its magnetic field must increase in strength, and that change in field strength produces the corresponding voltage according to the principle of electromagnetic self-induction.

What is the rate of energy storage in a Magnetic Inductor?

Thus, the power delivered to the inductor  $p = v \cdot i$  is also zero, which means that the rate of energy storage is zero as well. Therefore, the energy is only stored inside the inductor before its current reaches its maximum steady-state value,  $I_m$ . After the current becomes constant, the energy within the magnetic becomes constant as well.

Why do inductors behave differently than resistors?

Because inductors store the kinetic energy of moving electrons in the form of a magnetic field, they behave quite differently than resistors (which simply dissipate energy in the form of heat) in a circuit. Energy storage in an inductor is a function of the amount of current through it.

Why is an inductor discharging?

In this condition the inductor is said to be discharging, because its store of energy is decreasing as it releases energy from its magnetic field to the rest of the circuit. Note the polarity of the voltage with regard to the direction of current.

What are the dangers of an inductor in an electrical circuit?

An inductor in an electrical circuit can have undesirable consequences if no safety considerations are implemented. Some common hazards related to the energy stored in inductors are as follows: When an inductive circuit is completed, the inductor begins storing energy in its magnetic fields.

Example (PageIndex{A}) Design a 100-Henry air-wound inductor. Solution. Equation (3.2.11) says  $L = N^2 \mu A / l$ , so  $N$  and the form factor  $A/l$  must be chosen. Since  $A = (\pi)r^2$  is the area of a cylindrical inductor of ...

changes. For example, when the voltage becomes negative after crossing zero, S<sub>1</sub> changes from being switched on as the inductance energy storage to its body diode conduction to supply power for the load, while S<sub>2</sub> changes in the opposite function. Therefore, the functions of the two switches are complementary and interchange-

As the current through the inductor changes, the magnetic field also changes, and energy is either stored or released. The energy stored in an inductor can be expressed as:  $W = (1/2) * L * I^2$ . where: W = Energy stored in the inductor (joules, J) L = Inductance of the inductor (henries, H) I = Current through the inductor (amperes, A)

Energy Storage in Capacitors (contd.)  $W = \frac{1}{2} C V^2$  It shows that the energy stored within a capacitor is proportional to the product of its capacitance and the squared value of the voltage across the capacitor. energy applied to the inductor has now been converted into magnetic energy and is stored in the magnetic field set up around the inductor. If the voltage applied to the inductor is now switched off, the energy stored in the magnetic field is released back into the coils of the inductor, this time there is no opposing supply voltage applied so
