What is the most exotic material for a power inductor?

The most exotic material is cobalt-iron-vanadium(supermendur),reaching up to 2.2T. There is nothing higher. The power inductor gap may be realized in one of two fashions,discrete or distributed. Distributed gap materials are powder cores.

Why do inductor cores have a distributed air gap?

The individual powder particles are insulated from one another, allowing the cores to have inherently distributed air gaps for energy storagein an inductor. This distributed air gap property ensures that the energy are stored evenly through the core. This makes the core have a better temperature stability.

What makes a good power inductor?

A carefully considered power inductor is often a key design element to achieve a small, efficient, and cost-effective converter. For many inductor applications, powder cores are clearly superior compared with alternative core materials, such as ferrites or steel laminations.

How to choose a powder core inductor?

The inductor designer must meet the energy storage (inductance) requirement, as well as requirements for total loss, space, cost, EMI, fault-tolerance, temperature performance, and reliability. In the many cases powder cores have the clear advantage. Then the designer has a variety of options in choosing among the powder cores.

Which inductor core is best?

The Kool Mm E-core is the lowest cost option of the four, while the MPP toroid's advantage in size and efficiency is offset by being highest in cost. The High Flux core and MPP are the same size, and will be similar in price, since 14m powders are more costly to produce and to press than 26m powders. Conclusion: So what is the best inductor core?

How do power inductors work?

Power inductors require the presence of an air gapwithin the core structure. The purpose of the gap is to store the energy, and to prevent the core from saturating under load. Another way to express the function of the air gap is to say that it reduces and controls the effective permeability of the magnetic structure.

lower the energy storage capability is for a given size core * As the % of Ripple Current increases, the greater the core loss will become. A larger core, lower permeability or a completely different core material may be necessary to assure longevity * Temperature Rise of the Magnetic component will set the maximum safe ambient temperature
