

How does a triangular tube improve energy storage/release capacity?

Energy storage/release capacity improved by 0.15 % to 12 % with the triangular tube. Phase change materials (PCMs) play a critical role in energy storage systems due to their high latent heat capacity, enabling efficient thermal energy storage and release during phase transitions.

Which multi-tube lhes has the highest energy storage/release capacity?

Multi-tube LHES with various geometries using metal foam-enhanced PCM is analyzed. The triangular tube achieved the highest reduction in charge time at 10.4 %. The square tube achieved the highest reduction in discharge time at 27.8 %. The triple triangle tube provided the greatest energy storage/release capacities.

Does number of tubes affect energy storage and release capacity?

The energy storage and release capacity during melting and solidification processes did not increase proportionally with the number of tubes. In the quadruple-tube model, heat energy was distributed more uniformly within the PCM container.

What is a latent thermal energy storage (LTES)?

In a latent thermal energy storage (LTES), which utilizes the phase change on the storage material side, the latent heat of fusion stores large amounts of energy per unit volume in a narrow temperature range. Various concepts for storing thermal energy in phase change materials (PCMs) have been discussed in general by Cabeza .

Does tube geometry affect multi-tube energy storage enhanced with metal foam?

In the presented study, the interaction between the number of tubes and tube geometry in multi-tube energy storage enhanced with metal foam was investigated in terms of charge/discharge time, temperature change, and heat storage/release capacity. The main conclusions obtained are given below:

Can a vertical finned tube latent thermal energy storage system be calibrated?

It allowed for fast large-scale modeling of vertical finned tube latent thermal energy storage systems. This enables parameter and design studies, which have the potential to increase efficiency and reduce costs. Our outlook is as follows: The effective fin model can be calibrated to various fin types.

According to the number of tubes, the traditional latent heat energy storage system is divided into double-tube heat exchange system and triplex-tube heat exchange system. In addition to the inner tube where heat transfer fluid (HTF) flows, the triplex-tube heat exchange system also has an annular channel containing HTF outside PCM.

The triple triangle-tube design revealed enhancements in energy storage capacity of 0.41 % to 12 % and energy release capacity of 0.15 % to 9.93 % compared to other single and multiple-tube designs. Highlights An experimental investigation was initiated to investigate the thermal resistance in thermal storage systems. These systems comprise of phase change materials and tubes filled with heat transfer fluid. The merits of the e-NTU concept for this case was also investigated and found to be applicable. Experimental results proved that a tube-in-tank ...

Compared to the extensive attentions paid to latent heat thermal energy storage (LHTES) with single tube in shell, the configurations of multiple serpentine tubes as bundles are less explored. ... At the small HTF inlet mass flow rate (\dot{m} in) of 0.167 kg/s and a large tube pitch of 0.340 m, Reynolds number (Re) plays the dominant role in ...

Given the growing scarcity of energy resources, energy storage has become increasingly important to researchers. In this context, numerical simulations are employed to ...

The latent thermal energy storage system of the shell-and-tube type during charging and discharging has been analysed in this paper. An experimental and numerical investigation of transient forced convective heat transfer between the heat transfer fluid (HTF) with moderate Prandtl numbers and the tube wall, heat conduction through the wall and solid-liquid ...

The energy storage capacity of fluctuating heat sources decreases with the rise of the fluctuating amplitude. The energy storage capacity for $A = 50 \text{ K}$ and $A = 150 \text{ K}$ is 4.5% and 28.5% smaller than that of constant heat source, respectively. The reason is related to the temperature distribution of PCM during the melting process shown in Fig. 14

Latent thermal energy storage (LTS) systems are versatile due to their high-energy storage density within a small temperature range. In shell-and-tube type storage systems fins can be used in order to achieve enhanced charging and ...

Limited by the low thermal conductivity of PCMs, however, the large-scale applications of LHTES system are restricted to a certain extent. A multitude of enhancement technologies are therefore developed to improve the heat transfer performance in thermal energy storage devices, which includes the use of extended fins, addition of high conductivity ...

Also, the energy storage rate is higher for cases with more HTF tubes due to providing more distributed heat sources (Cases 4-6). Furthermore, using petal shaped tube rather than circular tube raises the rate of stored energy. Besides, for cases having more number of petals, energy storage rate is higher (Cases 7-9).

Fig. 11 shows the energy storage curve for examined configurations (case-1 to case-4) of different fin heights. It showed that the incorporation of longitudinal fins shifted the curve towards the left side which indicated faster storage of energy. The bare tube case could store maximum energy of 710 kJ that was the highest amongst all examined ...

Additionally, optimizing the tube arrangement by adding 22 tube passes can increase the energy storage efficiency except causing a marginal increase in reaction time. Among the factors analyzed, reactant porosity has the most significant impact on the heat storage time, while the HTF temperature determinates the heat exchange rate and energy ...

While the total energy storage capacity is determined by the PCM type, the number of tubes significantly influences the rate at which this energy is stored and released. ...

opens up new opportunities for stationary energy storage. Large-scale electrochemical energy storage system is critical for the renewable energy and smart grid technologies [1-3]. In particular, rechargeable batteries with low cost, long lifespan, good safety and high power density are required for stationary energy storage [4-6].

PCM materials are used for the thermal management of electrical system [3, 4], Trombe walls [5], cold storage [6], solar water heating [7], etc. Xie et al.
