What does a mechanical button on an interrupt do?

@Bimpelrekkie A mechanical button on an interrupt is asking for trouble unless it's very carefully debounced... If your button is a piezo switch, then the only power required is the power generated by pressing the button. For example: R2/C1 collect the energy produced by pressing the piezo. D1 prevents the C1 voltage getting too high.

How can I reduce the current flow when a button is pushed?

In either case, when the button is pushed, the total current value that flows depends on the resistor value. To minimize it (the current), I could increase the resistor value but not so much since, if I am right, it also depends on the input pin leakage value. Plus, a large resistor would recover slowly.

Why is power used during a refresh pulse?

Power is briefly used during the refresh pulse, both to recharge the capacitors and through the resistor and switch if it is closed. However, the length of the refresh pulse is short and the polling frequency results in the refresh current being relatively insignificant. Obviously this method is an active one.

What happens if a pin is pressed on a refresh button?

When configured properly, if the button is pressed the charge on the pin will discharge faster than the refresh rate. That condition can then be detected as part of the refresh algorithm as a read before refresh operation, or used to drive an interrupt.
