Will heated sand be the answer to energy storage needs?

Anyone who has ever hot-footed it barefoot across the beach on a sunny day walks away with a greater understanding of just how much heat sand can retain. That ability is expected to play a vital role in the future, as technology involving heated sand becomes part of the answer to energy storage needs.

Can a sand battery save energy?

The sand stores the heat up to 500°C which can then be used to warm homes in winter when energy costs are more expensive. This sand battery has provided a solution to the problem of year-round supply being a major issue for green energy and could have huge implications with regards to renewable energy storage in the future.

How do sand heaters work?

Patented technology developed and prototyped at NREL reveals how heaters powered by renewable energy sources like wind and solar can raise the temperature of sand particles to the desired temperature. The sand is then deposited into a silo for storage and use later, either to generate electricity or for process heat in industrial applications.

How does a sand battery work?

This sand battery was designed to store green energy for months at a time, and it worked successfully. The sand battery is charged up by heat made from electricity generated from solar or wind power sources. The sand stores the heat up to 500°C which can then be used to warm homes in winter when energy costs are more expensive.

Since the melting temperature of sand is high, it can be used to store increased amounts of heat and also for extensive periods of time, running into months, before it is used again.

The sand or the recycled glass is melted, typically with soda ash, so the melting point is lowered. Lowering the melting point improves the efficiency of the flat glass manufacturing process because it means that less heat is
