How can smart substations help manage a large power grid?

Estimation of the Overall Grid Status Regionally collected datafrom modern smart substations, through the routed messages (routed GOOSE and SV), can help to manage protection and control strategies in real time with large power grids.

How can smart substation data be used in real-time?

Regionally collected data from modern smart substations, through the routed messages (routed GOOSE and SV), can help to manage protection and control strategies in real time with large power grids. The overall state of the grid therefore can be estimated before appearance of reliability issues, such as cascaded failure or blackouts.

How can a smart grid be monitored in real-time?

Reliability of the electrical power service therefore can be monitored in real-time. Modern SAS are smarter with software enabled devices, digital sampling and seamless communication networks. These systems provide useful information for the smart grid applications and components.

Why do we need modern substation data?

The maintenance of the grid shall benefit from modern substations data as the later forms an important source of failure data. For instance, the IEC 61850 object models provide datasets that contain status of equipment at many levels in the substation.

How can a smart grid be scalable?

The smart grid can use SAS features to rapidly deploy several services and functions in transmission and distribution networks and control centers. One function can be to protect a network of connected renewable energy resources. Hence, the grid becomes scalable with these new SAS functionalities.

What are the benefits of smart grid evolution?

The following points highlight most important benefits for the smart grid evolution: Availability of Massive Data for Measurement and MeteringWith modern SAS systems, availability of digital measurement and metering helps to provide precise information about the grid status when these parameters are collected in regional or national level.

Incorporating IEC 61850 substation automation systems enable local and remote control and monitoring of all power assets as well as enterprise-wide data integration for efficient power system management - i.e., the smart grid.

The architecture of a smart grid system consists of various components like energy storage, smart meter, smart substation, distributed generation, phasor measure units, integrated communications, etc. Recent developments in this system include grid tools for smart charging of electric vehicles, electricity theft detection in power
