

How does an inductor store energy?

An inductor stores energy in its magnetic field. As the current through the inductor increases, it forces the magnetic lines of force to expand against their natural tendency to shorten. This expansion stores energy in the magnetic field, similar to how a rubber band stores energy when stretched.

How does a pure inductor work?

This energy is actually stored in the magnetic field generated by the current flowing through the inductor. In a pure inductor, the energy is stored without loss, and is returned to the rest of the circuit when the current through the inductor is ramped down, and its associated magnetic field collapses. Consider a simple solenoid.

How is the energy stored in an inductor calculated?

The energy stored in the magnetic field of an inductor can be written as $E = 0.5 \cdot L \cdot I^2$, where L is the inductance and I is the current flowing through the inductor.

What if an inductor is connected to a source?

Suppose an inductor is connected to a source and then the source is disconnected. The inductor will have energy stored in the form of magnetic field. But there is no way/path to discharge this energy? Short answer: It will find a way/path to discharge this energy. Longer answer:

When does the energy stored by an inductor stop increasing?

The energy stored by the inductor increases only while the current is building up to its steady-state value. When the current in a practical inductor reaches its steady-state value of $I_m = E/R$, the magnetic field ceases to expand.

What is the rate of energy storage in a Magnetic Inductor?

Thus, the power delivered to the inductor $p = v \cdot i$ is also zero, which means that the rate of energy storage is zero as well. Therefore, the energy is only stored inside the inductor before its current reaches its maximum steady-state value, I_m . After the current becomes constant, the energy within the magnetic becomes constant as well.
