How is energy stored in a capacitor absorbed by a resitor?

The energy stored in the capacitor is being absorbed by the resistor. by the resistor. An inductor is an element which stores a magnetic field. An inductor is a wire coiled around a material called a core. The core is typically made of a magnetic material however the core can be anything from a toilet paper roll to a piece of wood.

How does a capacitor store energy?

itors6.2.1. A capacitor is a passive element designed to store energy in i s elec ric eld. The word capacitor is derived from this element's capacity to store energy.6.2.2. When a voltage source v(t) is connected across the capacitor,the amo nt of charge stored,represented by q,is directly proportional to v(t),i.e.,q(t) = C

Why is charge on a capacitor continuous?

Charge on a capacitor can not instantly leave. It takes some finite amount of time for the charge to leave the plate. Therefore charge on the capacitor is continuous. Since V = q/C then voltage across a capacitor is also continuous. (i.e. The voltage across a capacitor can never change instantaneously.)

The initial energy is the energy in the 220uF capacitor at 10V and that energy is W = (1/2)*C*V^2 = 0.5*220u*10^2 = 11mJ. That is the solution to the (a) part. Here the 220uF ...

From the definition of voltage as the energy per unit charge, one might expect that the energy stored on this ideal capacitor would be just QV. That is, all the work done on the charge in moving it from one plate to the other would appear as energy stored. But in fact, the expression above shows that just half of that work appears as energy stored in the capacitor.

To find the current in the capacitor we have to apply KCL at the marked node: i 1 = i + i C 0A = 2A + i C i C = -2A dV/dt = i C /C = -2A/(.25F) = -8V/s dV/dt is negative, therefore for t>0 the capacitor is discharging. The energy stored in ...
