# No-load consumption of energy storage inverter

What is the no-load power of my inverter?

You can find no-load power (watts)mentioned on the specification sheet. To determine how much power your inverter is drawing without any load, multiply the battery voltage by the inverter no load current draw rating. For example, Battery voltage = 1000 watts Inverter = 24V

How much power does an inverter draw without a load?

To find out how much power your inverter draws without any load, multiply the battery voltage by the inverter's no load current draw rating. For example, if the battery voltage is 24V and the no load current is 0.4A, then the power drawn would be 24V \* 0.4A = 9.6W.

What is the no load current draw rating of the inverter?

To determine how much power your inverter is drawing without any load, multiply the battery voltage by the inverter no load current draw rating. For example, Battery voltage = 1000 watts Inverter = 24V No load current = 0.4 watts Power drawn = 24V \* 0.4 = 9.6 watts

How do I find the no load current of my inverter?

To determine the no load current of your inverter, look for the specification mentioned as no load current draw (amps) or no-load power (watts) on the inverter's specification sheet. Then, multiply the battery voltage by the inverter's no load current draw rating to find the power it draws without any load. For example, if your battery voltage is 24V, and the inverter's no load current draw is 2 amps, then the no load power would be 48 watts (24V \*2A).

How much power does an inverter draw from a battery?

The amount of power drawn from a battery by an inverter, even when there is no load attached, is called the " idle" or " no-load" consumption of the inverter. The average draw from the batteries when an inverter is turned on with no load attached depends on the efficiency of the inverter and its standby power consumption.

What is the no load current of a 1000 watt 24V inverter?

A 1000 watt 24V inverter with a 0.4 no load currenthas a power consumption of 9.6 watts. 24V x 0.4 = 9.6 watts

A 3000W inverter's power consumption depends on the load connected to it and the efficiency of the inverter. When no load is connected, a 3000W inverter may consume around 20 watts of power just to run itself. The ...

This will be even more noticeable when the energy consumption occurs mainly in the mornings and the evenings. When most of the energy consumption occurs during the day - say in an office with air-conditioning - a grid-tie inverter will be more efficient. After (very efficient) conversion to AC, the air-conditioning unit

Today I powered up for the first time my new Victron Quattro 48/10000/140-100/100. With no Ac load on the inverter. I only had the battery wired to inverter and no other DC loads (just the victron BMV 712 meter) that consumes just 1w with it's back light on. Inverter on no load consumption was showing 100w or just under 2A load on the battery.

Many inverters have a automatic standby mode. They shutdown inverter to save idle power and wake up every so often to see if an AC output load exists. Issue with standby mode is it takes a minimum output AC load to be detected by inverter. A light load may not be recognized and inverter will just continue its intermittant active-sleep cycle.
