Abstract. The building sector is responsible for a third of the global energy consumption and a quarter of greenhouse gas emissions. Phase change materials (PCMs) have shown high potential for latent thermal energy storage (LTES) through their integration in building materials, with the aim of enhancing the efficient use of energy.

A PCM is typically defined as a material that stores energy through a phase change. In this study, they are classified as sensible heat storage, latent heat storage, and thermochemical storage materials based on their heat absorption forms (Fig. 1). Researchers have investigated the energy density and cold-storage efficiency of various PCMs [[1], [2], [3], [4]].
