

Are materials defects energy storage units?

Energy storage occurs in a variety of physical and chemical processes. In particular, defects in materials can be regarded as energy storage units since they are long-lived and require energy to be formed. Here, we investigate energy storage in non-equilibrium populations of materials defects, such as those generated by bombardment or irradiation.

How much energy can a defect store?

Even a small and readily achievable defect concentration of 0.1 at.% can store energy densities of up to ~0.5 MJ/L and ~0.15 MJ/kg. Practical aspects, devices, and engineering challenges for storing and releasing energy using defects are discussed. The main challenges for defect energy storage appear to be practical rather than conceptual.

What are the roles of crystal defects in energy storage and conversion systems?

Generally speaking, according to the nature of crystal defect engineering, the main roles of defects in energy storage and conversion systems can be summarized as follows (Fig. 12): (I) Crystal defects can be exploited as energy storage/adsorption/active/nucleation sites.

Do defects achieve stored energy?

The stored energy values for 0.1-1 at.% defect concentrations, which can be achieved routinely with bombardment or irradiation, show that defects in materials, if properly engineered, may achieve stored energies comparable with those of state-of-the-art technologies.
