

The development prospects of negative electrodes for energy storage batteries

What are the recent trends in electrode materials for Li-ion batteries?

This mini-review discusses the recent trends in electrode materials for Li-ion batteries. Elemental doping and coatings have modified many of the commonly used electrode materials, which are used either as anode or cathode materials. This has led to the high diffusivity of Li ions, ionic mobility and conductivity apart from specific capacity.

What is an example of a negative electrode material?

For example, Leng et al. prepared graphene-LTO negative electrode materials by anchoring LTO on conducting graphene nanosheets formed using solvothermal and heat treatment steps, the LIBSC was fabricated with the electrolyte of 1 M LiPF₆, the positive electrode of three-dimensional graphene.

What is the difference between a battery and battery-type electrode?

In contrast, the battery-type materials have a relatively high energy density, but their application is limited by the low conductivity, large volume expansion, slow diffusion of ions in the body phase of the electrode materials during the charge/discharge process. This will lead to a low energy density in a small current.

Why are electrode properties important?

The study of electrode properties is crucial for the design and optimization of efficient and effective electrochemical energy storage. One of the key factors that influence the performance of these devices is the interaction between all electrode materials.

How can electrode performance be improved?

Techniques to improve electrode performance have been covered. Recently reported newer materials have been covered. In recent years, the primary power sources for portable electronic devices are lithium ion batteries.

Why do we use nanostructured materials as active electrodes?

Utilization of nanostructured materials and as active electrodes can be beneficial for the betterment of high rate operations, which enables the facile diffusion of electrolyte-ions, high surface to volume ratio.

The FIB cell reaction differs from cation-based batteries as it is an anion-based battery that uses negative monovalent fluoride-ions as carriers shuttling between the positive and negative electrodes, as shown in Fig. 2 operates on a similar principle to cation-based batteries (such as LIBs), and is commonly referred to as a "rocking chair battery".
