

What are the functions of the energy storage electromagnetic catapult

How much electricity does an electromagnetic catapult use?

The same energy is then used to return the carriage to its starting position. An electromagnetic catapult can launch every 45 seconds. Each three-second launch can consume as much as 100 million wattsof electricity,about as much as a small town uses in the same amount of time.

Can electromagnetic catapult technology be used to launch aircraft?

Electromagnetic catapult technology already has the ability to launch any aircraftnow in the Navy inventory and any the Navy has ordered. With the new launch system's potential to achieve acceleration forces reaching 14 Gs,human endurance may be one of the few limitations it faces.

Do electromagnetic catapults need more manpower?

Massive systems that require significant manpower to operate and maintain,they are reaching the limits of their abilities,especially as aircraft continue to gain weight. Electromagnetic catapults will require less manpowerto operate and improve reliability; they should also lengthen aircraft service life by being gentler on airframes.

How does a catapult work?

After hooking up to the carriage, aircraft are electro-magnetically pushed and pulled down the catapult until airborne. After releasing an aircraft at speeds approaching 200 mph, the carriage will come to a stop in only 20 feet, its forward movement countered by reversing the push-pull electromagnetic forces of the two beams.

What is a launch control system for electromagnetic catapults?

The launch control system for electromagnetic catapults, on the other hand, will know what speed an aircraft should have at any point during the launch sequence, and can make adjustments during the process to ensure that an aircraft will be within 3 mph of the desired takeoff speed.

What is a shipboard electromagnetic catapult?

Shipboard electromagnetic catapults will be based on larger linear induction motors,made up of three main parts: two 300-foot-long stationary beams,or stators,spaced a couple of inches apart,and a 20-foot-long carriage,or shuttle,that is sandwiched between the two beams and can slide back and forth along their lengths.
