The growing interest in energy-efficient buildings has spurred research into the latent heat storage capacity of cementitious materials. This involves incorporating phase change materials (PCMs) within the matrix, allowing the materials to absorb, store, and release thermal energy, thereby moderating temperature fluctuations in buildings [183], [76], [155], [164].

Recently, direct recovery for spent LIBs makes the closed-loop circulation of electrode materials due to the direct use of degraded active materials as raw materials to produce fresh active materials. Thus its underlying sustainability of using less chemical agents and energy cost has increasingly attracted attentions from battery community.
